# A seemingly unprecedented event might make one ask

- ① What does it resemble from the past?
- ② What past events are most relevant?
- ③ Can we incorporate past events in a systematic, principled manner?

# When would we ever have to do this?

- Event-driven investing strategies (unscheduled news shock)
- Pairs trading strategies
- Structural shock to macroeconomic conditions (scheduled news possibly pre-empted by news shock)
- Biomedical panel data subject to exogenous shock or interference

## Example (Weekend of March 6th - 8th, 2020)

# Oil nose-dives as Saudi Arabia and Russia set off 'scorched earth' price war

PUBLISHED SUN, MAR 8 2020-9:01 AM EDT | UPDATED MON, MAR 9 2020-5:33 PM EDT

## Oil crashes by most since 1991 as Saudi Arabia launches price war

By [Matt Egan](#), CNN Business

🕒 3 minute read · Updated 3:21 PM EDT, Mon March 9, 2020

# Punchline of the paper

Forecasting is possible under news shocks, so long as we incorporate external information to account for the nonzero errors.

# Background and related methods

## Volatility Modeling

- GARCH is slow to react (Andersen et al. [2003](#))
- Asymmetric GARCH models catch up faster but need post-shock data
- Realized GARCH (Hansen, Huang, and Shek [2012](#)), in our setting, would require post-shock information and/or high-frequency data in order to outperform, and Realized GARCH is highly parameterized

# Background and related methods

## Forecast Augmentation

- Clements and Hendry [1998](#); Clements and Hendry [1996](#) laid the groundwork for modeling nonzero errors in time series forecasting
- Guerrón-Quintana and Zhong [2017](#) use a series' own errors to correct the forecast for that series
- Dendramis, Kapetanios, and Marcellino [2020](#) use a similarity-based procedure to correct linear parameters in time series forecasts
- Foroni, Marcellino, and Stevanovic [2022](#) adjust pandemic-era forecasts using intercept correction techniques and data from Great Financial Crisis
- Lin and Eck [2021](#) use distanced-based weighting (a similarity approach) to aggregate and weight fixed effects from a donor pool

# Outline

- 1 Introduction
- 2 Setting
- 3 Post-shock Synthetic Volatility Forecasting Methodology
- 4 Properties of Volatility Shock and Shock Estimators
- 5 Real Data Example
- 6 Numerical Examples
- 7 Discussion
- 8 Future directions for Synthetic Volatility Forecasting
- 9 Supplement

# The news has broken but markets are closed

- After-hours trading provides a poor forum in which to digest news
- The news constitutes public, material information relevant to one or more traded assets
- The qualitative aspects of the news provide basis upon which to match to past events

# A Primer on GARCH

Let  $\{a_t\}$  denote an observable, real-valued discrete-time stochastic process. We say  $\{a_t\}$  is a strong GARCH process with respect to  $\{\epsilon_t\}$  iff

$$\sigma_t^2 = \omega + \sum_{k=1}^m \alpha_k a_{t-k}^2 + \sum_{j=1}^s \beta_j \sigma_{t-j}^2$$

$$a_t = \sigma_t \epsilon_t$$

$$\epsilon_t \stackrel{iid}{\sim} E[\epsilon_t] = 0, \text{Var}[\epsilon_t] = 1$$

$$\forall k, j, \alpha_k, \beta_j \geq 0$$

$$\forall t, \omega, \sigma_t > 0$$

# Model Preliminaries

Let  $I(\cdot)$  be an indicator function.

Let  $T_i$  denote the time length of the time series  $i$  for  $i = 1, \dots, n + 1$ .

Let  $T_i^*$  denote the largest time index prior to the arrival of the news shock, with  $T_i^* < T_i$ .

Let  $\delta, \mathbf{x}_{i,t} \in \mathbb{R}^p$ .

# Model Setup

For  $t = 1, \dots, T_i$  and  $i = 1, \dots, n + 1$ , the model  $\mathcal{M}_1$  is defined as

$$\sigma_{i,t}^2 = \omega_i + \omega_i^* + \sum_{k=1}^{m_i} \alpha_{i,k} a_{i,t-k}^2 + \sum_{j=1}^{s_i} \beta_{i,j} \sigma_{i,t-j}^2 + \gamma_i^T \mathbf{x}_{i,t}$$

$$\mathcal{M}_1: \quad a_{i,t} = \sigma_{i,t}((1 - D_{i,t}^{\text{return}})\epsilon_{i,t} + D_{i,t}^{\text{return}}\epsilon_i^*)$$

$$\omega_{i,t}^* = D_{i,t}^{\text{vol}}[\mu_{\omega^*} + \delta' \mathbf{x}_{i,t-1} + u_{i,t}],$$

with error structure

$$\epsilon_{i,t} \stackrel{iid}{\sim} \mathcal{F}_{\epsilon} \text{ with } \mathbb{E}_{\mathcal{F}_{\epsilon}}(\epsilon) = 0, \text{Var}_{\mathcal{F}_{\epsilon}}(\epsilon) = 1$$

$$\epsilon_{i,t}^* \stackrel{iid}{\sim} \mathcal{F}_{\epsilon^*} \text{ with } \mathbb{E}_{\mathcal{F}_{\epsilon^*}}(\epsilon) = \mu_{\epsilon^*}, \text{Var}_{\mathcal{F}_{\epsilon^*}}(\epsilon^*) = \sigma_{\epsilon^*}^2$$

$$u_{i,t} \stackrel{iid}{\sim} \mathcal{F}_u \text{ with } \mathbb{E}_{\mathcal{F}_u}(u) = 0, \text{Var}_{\mathcal{F}_u}(u) = \sigma_u^2$$

$$\epsilon_{i,t} \perp\!\!\!\perp \epsilon_{i,t}^* \perp\!\!\!\perp u_{i,t}$$

where  $D_{i,t}^{\text{return}} = I(t \in \{T_i^* + 1, \dots, T_i^* + L_{i,\text{return}}\})$  and  $D_{i,t}^{\text{vol}} = I(t \in \{T_i^* + 1, \dots, T_i^* + L_{i,\text{vol}}\})$  and  $L_{i,\text{return}}, L_{i,\text{vol}}$  denote the lengths of the log return and volatility shocks, respectively. Let  $\mathcal{M}_0$  denote the subclass of  $\mathcal{M}_1$  models such that  $\delta \equiv 0$ . Note

# Our Model is Nested Within GARCH-X

Populate once notational details are decided.

# Volatility Profile of a Time Series

$$V_t = \begin{pmatrix} \alpha_{1,t} & \alpha_{1,2} & \cdots & \alpha_{1,n} \\ \beta_{1,t} & \beta_{1,2} & \cdots & \beta_{1,n} \\ \vdots & \vdots & \ddots & \vdots \\ RV_{1,t} & RV_{2,t} & \cdots & RV_{n,t} \\ RV_{1,t}-1 & RV_{2,t}-1 & \cdots & RV_{n,t}-1 \\ \vdots & \vdots & \ddots & \vdots \\ IV_{1,t} & IV_{2,t} & \cdots & IV_{n,t} \\ IV_{1,t}-1 & IV_{2,t}-1 & \cdots & IV_{n,t}-1 \\ \vdots & \vdots & \ddots & \vdots \\ |r_{1,t}| & |r_{2,t}| & \cdots & |r_{n,t}| \\ |r_{1,t}-1| & |r_{2,t}-1| & \cdots & |r_{n,t}-1| \\ \vdots & \vdots & \ddots & \vdots \\ \text{Volume}_{1,t} & \text{Volume}_{2,t} & \cdots & \text{Volume}_{n,t} \\ \text{Volume}_{1,t}-1 & \text{Volume}_{2,t}-1 & \cdots & \text{Volume}_{n,t}-1 \end{pmatrix},$$

# What's the method here?

$$2 = 2$$

# Forecasting

We present two forecasts:

$$\text{Forecast 1: } \hat{\sigma}_{unadjusted}^2 = \hat{\mathbb{E}}_{T^*}[\sigma_{i,T^*+1}^2 | \mathcal{F}_{T^*}] = \hat{\omega}_i + \sum_{k=1}^{m_i} \hat{\alpha}_{i,k} a_{i,t-k}^2 + \sum_{j=1}^{s_i} \hat{\beta}_{i,j} \sigma_{i,j}^2$$

$$\text{Forecast 2: } \hat{\sigma}_{adjusted}^2 = \hat{\mathbb{E}}_{T^*}[\sigma_{i,T^*+1}^2 | \mathcal{F}_{T^*}] + \hat{\omega}^* = \hat{\omega}_i + \sum_{k=1}^{m_i} \hat{\alpha}_{i,k} a_{i,t-k}^2 + \sum_{j=1}^{s_i} \hat{\beta}_{i,j} \sigma_{i,j}^2$$

# Excess Volatility Estimators

Following Abadie, Diamond, and Hainmueller [2010](#); Abadie and Gardeazabal [2003](#), let  $\|\cdot\|_S$  denote any semi-norm on  $\mathbb{R}^P$ , and define

$$\{\pi\}_{i=2}^{n+1} = \arg \min_{\pi} \|\mathbf{v}_1 - \mathbf{V}_t \pi\|_S .$$

# Ground Truth Estimators

# Loss Functions

# Simplest Simulation Setup

We also have simulations for...

# Additional Simulations

# Alternative Data-Generating Processes

- Could we do all of the above with high-frequency data?
- Realized GARCH with High-Frequency Data
- Stochastic Volatility

# Alternative Estimators and Estimands in Volatility Modeling

- Realized GARCH with High-Frequency Data
- Overnight returns instead of open-to-close
- Value-at-Risk using SVF-based  $\hat{\sigma}_t^2$
- Signal Recovery Perspective (Ferwana and Varshney [2022](#))
- Stochastic Volatility: Correlation between errors

# New Frontiers in Aggregation Methods

- Integrate lessons from literature on under/over reactions to information shocks (Jiang and Zhu [2017](#))
- Synthetic Impulse Response Functions

# Synthetic Impulse Response Functions: A Proposal

- Suppose we have a multivariate time series of dimension  $p \times \text{times } T$  subject to shocks from a common shock distribution
- Using an IRF estimate aggregated from the first  $n$  shocks of interest, we predict the response of variable  $i$  from variable  $j$ ,  $1 \leq i \leq j \leq p$ .

We analyze the real-world example with Brexit included.
