## Questions guiding these slides (remove later)

- 1 What have you learned? **Forecasting is difficult; Heterogeneity of DGP**
- 2 Why did you choose this topic? **Although it seems narrow, the question of “what if you had a new unit and had very little past information to go on” is a common phenomenon in statistics.** Examples: Shock to a time series Unscheduled scheduled A new seller joins amazon's platform, i.e. cold starts (Fatemi et al. [2023](#))
- 3 What does this contribute to the literature and econometrics more broadly?
- 4 How would you improve your work? **Many ideas here. There were more directions than I could pursue.**
- 5 Most common question asked is what you learned from the study you have done. You have to sum up your entire study in a few sentences and remember the technical terms you have mentioned in your research because that is what your examiner wants to hear from you.
- 6 Why did you choose this particular topic or what your inspiration behind this study was. This is one of the trickiest questions as you have to prove your convincing power to the panel of the teachers that what you did is valuable for the society and was worth their time.
- 7 Tell about how zealous you were about this particular problem.

## Questions guiding these slides (remove later)

- ① What is the importance of your study or how will it contribute or add up to the existing body of knowledge? **Two entirely separate perspectives: (1) Post-shock forecasting is a novel research framework. (2) Post-shock forecasting builds on intercept corrections and other canonical questions.**
- ② What type of background research have you done for the study?
- ③ What are the limitations you have faced while writing? **A ton of hyperparameters**
- ④ What will you include if you are told to add something extra to the study?  
**LLM-generated donors and covariates**
- ⑤ What are the recommendations of your study? **Relatively easy to answer: for an unprecedented event, locate it in the space of previous events.**
- ⑥ 10. What was your hypothesis and how did you framed it? **Signal to noise**

## Questions guiding these slides (remove later)

- 1 12. If given a chance, would like to do something different with your work?
- 2 13. What are the limitations you faced while dealing with your samples? **Realized volatility is something that can be estimated with HF data**
- 3 14. How did you relate your study to the existing theories?
- 4 15. What is the future scope of this study?
- 5 19. How did you evaluate your work? **Simulations and real data examples**
- 6 How would you improve your work? **By design, synthetic control cannot extrapolate. In the causal inference context, that may very well be a virtue. However, in the prediction context, it may hinder us. Note that random forest has the same problem.**

Premise: There is a breaking news at some fractional lag  $T-\epsilon$

- After-hours trading provides a poor forum in which to digest news
- News constitutes public, material information for one or more traded assets
- The **qualitative aspects** of the news provide a basis upon which to
  - match to past news shocks
  - match in a  $p$ -dimensional covariate space

# A Primer on GARCH

## Definition

Let  $\{a_t\}$  denote an observable, real-valued discrete-time stochastic process.

We call  $\{a_t\}$  a strong GARCH process (Francq and Zakoian 2019) with respect to  $\{\epsilon_t\}$  iff

$$\sigma_t^2 = \omega + \sum_{k=1}^m \alpha_k a_{t-k}^2 + \sum_{j=1}^s \beta_j \sigma_{t-j}^2$$

$$a_t = \sigma_t \epsilon_t$$

$$\epsilon_t \stackrel{iid}{\sim} E[\epsilon_t] = 0, \text{Var}[\epsilon_t] = 1$$

$$\forall k, j, \alpha_k, \beta_j \geq 0$$

$$\forall t, \omega, \sigma_t > 0$$

## Volatility Equation with an exogenous term: GARCH-X

$$\sigma_t^2 = \omega + \sum_{k=1}^m \alpha_k a_{t-k}^2 + \sum_{j=1}^s \beta_j \sigma_{t-j}^2 + \gamma^T \mathbf{x}_t .$$

We will be looking at only one exogenous term.

# Model Preliminaries

Let  $I(\cdot)$  be an indicator function.

Let  $T_i$  denote the time length of the time series  $i$  for  $i = 1, \dots, n + 1$ .

Let  $T_i^*$  denote the largest time index prior to news shock, with  $T_i^* < T_i$  (i.e. we assume at least one post-shock observation).

Let  $\delta, \mathbf{v}_{i,t} \in \mathbb{R}^p, \mathbf{x}_{i,t} \in \mathbb{R}^d$ .

# Model Setup

For  $t = 1, \dots, T_i$  and  $i = 1, \dots, n + 1$ , the model  $\mathcal{M}_1$  is defined as

$$\begin{aligned}\sigma_{i,t}^2 &= \omega_i + \omega_{i,t}^* + \sum_{k=1}^{m_i} \alpha_{i,k} a_{i,t-k}^2 + \sum_{j=1}^{s_i} \beta_{i,j} \sigma_{i,t-j}^2 + \gamma_i^T \mathbf{x}_{i,t} \\ \mathcal{M}_1: \quad a_{i,t} &= \sigma_{i,t}((1 - D_{i,t}^{\text{return}})\epsilon_{i,t} + D_{i,t}^{\text{return}}\epsilon_i^*) \\ \omega_{i,t}^* &= D_{i,t}^{\text{vol}}[\mu_{\omega^*} + \delta' \mathbf{v}_{i,t} + u_{i,t}],\end{aligned}$$

with error structure

$$\begin{aligned}\epsilon_{i,t} &\stackrel{iid}{\sim} \mathcal{F}_{\epsilon} \text{ with } \mathbb{E}_{\mathcal{F}_{\epsilon}}(\epsilon) = 0, \text{Var}_{\mathcal{F}_{\epsilon}}(\epsilon) = 1 \\ \epsilon_{i,t}^* &\stackrel{iid}{\sim} \mathcal{F}_{\epsilon^*} \text{ with } \mathbb{E}_{\mathcal{F}_{\epsilon^*}}(\epsilon) = \mu_{\epsilon^*}, \text{Var}_{\mathcal{F}_{\epsilon^*}}(\epsilon^*) = \sigma_{\epsilon^*}^2 \\ u_{i,t} &\stackrel{iid}{\sim} \mathcal{F}_u \text{ with } \mathbb{E}_{\mathcal{F}_u}(u) = 0, \text{Var}_{\mathcal{F}_u}(u) = \sigma_u^2 \\ \epsilon_{i,t} &\perp\!\!\!\perp \epsilon_{i,t}^* \perp\!\!\!\perp u_{i,t}\end{aligned}$$

where  $D_{i,t}^{\text{return}} = I(t \in \{T_i^* + 1, \dots, T_i^* + L_{i,\text{return}}\})$  and  $D_{i,t}^{\text{vol}} = I(t \in \{T_i^* + 1, \dots, T_i^* + L_{i,\text{vol}}\})$  and  $L_{i,\text{return}}, L_{i,\text{vol}}$  denote lengths of log return and volatility shocks, respectively.

Note: we will be looking GARCH(1,1) only in this presentation.

# Our Model is Nested inside a Factor Model

Consider  $\mathcal{M}_1$  in the context of the factor model from Abadie, Diamond, and Hainmueller 2010, where an untreated unit is governed by:

$$Y_{i,t}^N = \delta_t + \theta_t' \mathbf{Z}_i + \lambda_t' \boldsymbol{\mu}_i + \varepsilon_{i,t}$$

which nests the GARCH model's volatility equation as well as the ARMA representation of a GARCH model, where

$\delta_t \sim \omega$ , a location parameter shared across donors

$\theta_t \sim \boldsymbol{\alpha}_k$ , a vector of ARCH parameters and other coefficients shared across donors

$\mathbf{Z}_i \sim \mathbf{a}_{i,t-k}$ , a vector of observable quantities specific to each donor

$\lambda_t \sim \boldsymbol{\beta}_j$ , a vector of GARCH parameters shared across donors

$\boldsymbol{\mu}_i \sim \boldsymbol{\sigma}_{i,t-j}^2$ , a vector of latent quantities specific to each donor

# Volatility Profile of a Time Series

Consider the  $p \times n$  matrix that stores donor and covariate information at time  $t$

$$\mathbf{V}_t = \begin{pmatrix} \hat{\alpha}_{1,t} & \hat{\alpha}_{t,2} & \cdots & \hat{\alpha}_{t,n} \\ \hat{\beta}_{1,t} & \hat{\beta}_{t,2} & \cdots & \hat{\beta}_{t,n} \\ \vdots & \vdots & \ddots & \vdots \\ RV_{1,t} & RV_{2,t} & \cdots & RV_{n,t} \\ RV_{1,t-1} & RV_{2,t-1} & \cdots & RV_{n,t-1} \\ \vdots & \vdots & \ddots & \vdots \\ IV_{1,t} & IV_{2,t} & \cdots & IV_{n,t} \\ IV_{1,t-1} & IV_{2,t-1} & \cdots & IV_{n,t-1} \\ \vdots & \vdots & \ddots & \vdots \\ |r_{1,t}| & |r_{2,t}| & \cdots & |r_{n,t}| \\ |r_{1,t-1}| & |r_{2,t-1}| & \cdots & |r_{n,t-1}| \end{pmatrix},$$

where RV denotes realized variance and IV the implied volatility

# Significance of the Volatility Profile

Covariates chosen for inclusion in a given volatility profile may be any  $\mathcal{F}_t$ -measurable function, for example

- levels
- differences in levels
- log returns
- percentage returns
- measurable transformations of the above

Key criterion for inclusion: how plausible is the covariate as a **proxy for risk conditions** for the volatility series to be forecasted?

## Realized Volatility Estimation

Examine  $K$  units of time; each unit is divided into  $m$  intervals of length  $\frac{1}{m}$ . Let  $p_t = \log P_t$ , and let  $\tilde{r}(t, \frac{1}{m}) = p_t - p_{t-\frac{1}{m}}$  (Andersen and Benzoni 2008).

Estimate variance of  $i$ th log return series using Realized Volatility of the  $K$  consecutive trading days that conclude with day  $t$ , denoted  $RV_{i,t}^{K,m}$ , using

$$RV_{i,t}^{K,m} = \frac{1}{K} \sum_{v=1}^{Km} \tilde{r}^2(v/m, 1/m),$$

where the  $K$  trading days have been chopped into  $Km$  equally-sized blocks.

Assuming the  $K$  units  $\tilde{r}(t, 1) = p_t - p_{t-1}$  are s.t.  $\tilde{r}(t, 1) \stackrel{iid}{\sim} N(\mu, \delta^2)$ , it is easily verified that

$$\mathbb{E}[RV^{K,m}] = \frac{\mu^2}{m} + \delta^2,$$

which is a biased but consistent estimator of the variance. We pick  $m = 77$ , corresponding to the 6.5-hour trading day chopped into 5-minute blocks, omitting first five-minutes of the day.

# Forecasting

We present two forecasts:

$$\text{Forecast 1: } \hat{\sigma}_{unadjusted}^2 = \hat{\mathbb{E}}[\sigma_{1, T_1^*+1}^2 | \mathcal{F}_{T^*}] = \hat{\omega}_i + \sum_{k=1}^{m_i} \hat{\alpha}_{i,k} a_{i,t-k}^2 + \sum_{j=1}^{s_i} \hat{\beta}_{i,j} \sigma_{i,t-j}^2 + \hat{\gamma}_i^T \mathbf{x}_{i,t}$$

$$\text{Forecast 2: } \hat{\sigma}_{adjusted}^2 = \hat{\mathbb{E}}[\sigma_{1, T_1^*+1}^2 | \mathcal{F}_{T^*}] + \hat{\omega}^* = \hat{\omega}_i + \sum_{k=1}^{m_i} \hat{\alpha}_{i,k} a_{i,t-k}^2 + \sum_{j=1}^{s_i} \hat{\beta}_{i,j} \sigma_{i,t-j}^2 + \hat{\gamma}_i^T \mathbf{x}_{i,t} + \hat{\omega}^* .$$

# Excess Volatility Estimators

- Observe the pair  $(\{\hat{\omega}_i^*\}_{i=2}^{n+1}, \{\mathbf{v}_i\}_{i=2}^{n+1})$ .

## Excess Volatility Estimators

- Observe the pair  $(\{\hat{\omega}_i^*\}_{i=2}^{n+1}, \{\mathbf{v}_i\}_{i=2}^{n+1})$ .
- Goal: recover weights  $\{\pi_i\}_{i=2}^{n+1} \in \Delta^n$  and compute  $\hat{\omega}^* := \sum_{i=2}^{n+1} \pi_i \hat{\omega}_i^*$ , our forecast adjustment term.

# Excess Volatility Estimators

- Observe the pair  $(\{\hat{\omega}_i^*\}_{i=2}^{n+1}, \{\mathbf{v}_i\}_{i=2}^{n+1})$ .
- Goal: recover weights  $\{\pi_i\}_{i=2}^{n+1} \in \Delta^n$  and compute  $\hat{\omega}^* := \sum_{i=2}^{n+1} \pi_i \hat{\omega}_i^*$ , our forecast adjustment term.
- Following Abadie and Gardeazabal [2003](#), Abadie, Diamond, and Hainmueller [2010](#), let  $\|\cdot\|_S$  denote any semi-norm on  $\mathbb{R}^p$ , and define

$$\{\pi\}_{i=2}^{n+1} = \arg \min_{\pi} \|\mathbf{v}_{1,T^*} - \mathbf{V}_{T^*} \pi\|_S .$$

## Why apply our method to the 2016 US Election?

- You can win the US Presidency without a majority.
- No incumbent candidate
- Donald J. Trump espoused unorthodox, populist positions on healthcare, trade, foreign policy
- Donald J. Trump had no record to assess or criticize
- It was not predicted – hence it delivered news.

IYG

**iShares U.S. Financial Services ETF**

**Figure:** IYG includes JPM, BAC, WF, CITI, among other financial majors

- 1 **Model choice** GARCH(1,1) on the daily log return series of IYG in each donor
- 2 **Covariate Choice**
  - previous 30 log returns of IYG (large pre-treatment period, in the language of SC)
  - log return Crude Oil (CL.F)
  - VIX
  - log return of the VIX
  - log returns of the 3-month, 5-year, 10-year, and 30-year US Treasuries
  - return of the most recently available monthly spread between AAA and BAA corporate debt
  - log return in the trading volume of the ETF IYG itself
- 3 **Donor pool construction** US Elections from 2004, 2008, 2012
- 4 **Choice of estimator for volatility** Sum of 77 squared five-minute returns generated between 9:35am and 4pm on November 9th, 2016.

## 2016 Election

Figure: The volatility induced by the 2016 US election

# Formal Results

## Proposition

Assume

- ① For each  $i$ ,  $\{a_{i,t}\}_{t=0,\dots,T_i}$  obeys a GARCH- $X(m, s)$  with volatility shocks found in  $\mathcal{M}_1$ , where  $T_i$  is the length of the  $i$ th series.
- ② For each  $i$ ,  $\{\omega_{i,t}^*\}_{t=0,\dots,T_i}$  is potentially non-zero at  $\{T_i^* + 1, \dots, T_i^* + k\}$ ,  $\omega_{i,T^*+1}^* \equiv \dots \equiv \omega_{i,T^*+k}^*$ , and zero otherwise, where the arrival of  $T_i^*$  is governed by a time-invariant distribution on  $\{a_{i,t}\}_{t=0,\dots,T_i-1}$ .
- ③ The conditions in Assumption 0 of Han and Kristensen 2014 prevail.

Then for any  $i$ ,  $\hat{\omega}_{i,t}^* \xrightarrow{P} \omega_i^*$ .

## Proposition

Assume

- ① All conditions from the previous proposition.
- ② There exist weights  $\{\pi_i\}_{i=2}^{n+1}$  such that  $\mathbf{v}_{1,T^*} = \sum_{i=2}^{n+1} \pi_i \mathbf{v}_{i,T^*}$ .

Then  $\hat{\sigma}_{adjusted}^2 \xrightarrow{P} \sigma_{1,T^*+1}^2$ .

# Hypotheses to Test Via Simulations

Ceteris paribus...

- ① Distance-based weighting should **outperform** the unadjusted forecast as  $\delta$  increases (signal-to-noise)

# Hypotheses to Test Via Simulations

Ceteris paribus...

- 1 Distance-based weighting should **outperform** the unadjusted forecast as  $\delta$  increases (signal-to-noise)
- 2 Distance-based weighting should **underperform** as the variability in  $u_{i,t}$  increases (signal-to-noise)

# Hypotheses to Test Via Simulations

Ceteris paribus...

- ① Distance-based weighting should **outperform** the unadjusted forecast as  $\delta$  increases (signal-to-noise)
- ② Distance-based weighting should **underperform** as the variability in  $u_{i,t}$  increases (signal-to-noise)
- ③ Distance-based weighting should **outperform** the arithmetic mean as the variability of  $v_{i,T^*}$  increases between donors (importance of linear signal)

# Hypotheses to Test Via Simulations

Ceteris paribus...

- 1 Distance-based weighting should **outperform** the unadjusted forecast as  $\delta$  increases (signal-to-noise)
- 2 Distance-based weighting should **underperform** as the variability in  $u_{i,t}$  increases (signal-to-noise)
- 3 Distance-based weighting should **outperform** the arithmetic mean as the variability of  $v_{i,T^*}$  increases between donors (importance of linear signal)
- 4 Distance-based weighting should **underperform** the arithmetic mean as  $\mu_{\omega^*}$  increases (importance of linear signal)

# Hypotheses to Test Via Simulations

Ceteris paribus...

- ① Distance-based weighting should **outperform** the unadjusted forecast as  $\delta$  increases (signal-to-noise)
- ② Distance-based weighting should **underperform** as the variability in  $u_{i,t}$  increases (signal-to-noise)
- ③ Distance-based weighting should **outperform** the arithmetic mean as the variability of  $v_{i,T^*}$  increases between donors (importance of linear signal)
- ④ Distance-based weighting should **underperform** the arithmetic mean as  $\mu_{\omega^*}$  increases (importance of linear signal)
- ⑤ When  $D_{i,T^*+1}^{return} = 1 = D_{i,T^*+1}^{vol}$ , i.e. when there is both a **return shock** and **volatility shock**, our adjustment methods should **underperform** due to failed identification in  
 $a_{T^*+1} = \sigma_{T^*+1} \epsilon_{T^*+1}$

# Simplest Simulation Setup

Most elementary simulation regime tests Hypothesis 1 and 2 by varying  $\delta$  and  $u_{i,t}$ .

Recall an  $\mathcal{M}_1$  model on the volatility, which is characterized by an exogenous shock to the volatility equation generated by an affine function of the covariates:

$$\begin{aligned}\sigma_{i,t}^2 &= \omega_i + \omega_{i,t}^* + \sum_{k=1}^{m_i} \alpha_{i,k} a_{i,t-k}^2 + \sum_{j=1}^{s_i} \beta_{i,j} \sigma_{i,t-j}^2 + \gamma_i^T \mathbf{x}_{i,t} \\ \mathcal{M}_1: \quad a_{i,t} &= \sigma_{i,t}((1 - D_{i,t}^{return})\epsilon_{i,t} + D_{i,t}^{return}\epsilon_i^*) \\ \omega_{i,t}^* &= D_{i,t}^{vol}[\mu_{\omega^*} + \delta' \mathbf{v}_{i,t} + u_{i,t}] \\ D_{i,t}^{return} &\equiv 0\end{aligned}$$

We shall group the extensions into five buckets:

- How much can we automate?
- Alternatives for fixed effect estimation
- Alternative estimators and estimands
- What can you do with a volatility forecast?
- Where else is distanced-based weighting useful?
- Can we extend the results of (Bodilsen and Lunde [2023](#))

# How much can we automate?

## Use NLP to identify donors.

### You

What are some events that are similar to Chinese government's ban on iPhones for government officials in September 2023?

### ChatGPT

The Chinese government's ban on iPhones for government officials in September 2023 is a notable example of government-led restrictions or bans on certain technology products or services due to security concerns or political reasons. Here are some events or actions that are somewhat similar:

1. **Huawei Ban in the United States:** The United States government banned Huawei, a Chinese telecommunications company, from selling its equipment and infrastructure in the U.S. due to concerns about national security and espionage. This ban was initiated in 2019 and has had significant repercussions for Huawei's business globally.
2. **Russian Ban on Telegram:** In 2018, the Russian government banned Telegram, a popular messaging app, due to the company's refusal to provide encryption keys to Russian security agencies. The ban resulted in the disruption of Telegram services within Russia and sparked debates about privacy and government surveillance.
3. **India's Ban on Chinese Apps:** In 2020, the Indian government banned several Chinese mobile apps, including TikTok and WeChat, citing concerns about data privacy and national security after a border clash between Indian and Chinese troops. The ban affected millions of users and led to diplomatic tensions between India and China.
4. **Turkey's Wikipedia Ban:** In 2017, the Turkish government banned access to Wikipedia, alleging that the website was involved in a smear campaign against Turkey. The ban stemmed from Wikipedia's refusal to remove content that the Turkish government deemed offensive. Despite international criticism, the ban remained in place for over two years before being lifted in 2020.
5. **Iran's Ban on Messaging Apps:** The Iranian government has intermittently banned messaging apps such as Telegram and WhatsApp over concerns about the spread of misinformation, political dissent, and national security threats. These bans have been part of broader efforts to control online communication and social media platforms within Iran.

These examples demonstrate how governments may impose bans or restrictions on technology products, services, or platforms for various reasons, including national security, political control, and regulatory compliance.

# How much can we automate?

What if the variables in the volatility profile are difficult to specify?

Proposed solution:

Use shrinkage estimation to detect fleeting signals in the cross section of  $a_t^2$  (Chinco, Clark-Joseph, and Ye [2019](#)).

# Alternative Ways of Estimating Fixed Effects

High-frequency data?

- Realized GARCH with High-Frequency Data
- Stochastic Volatility

# Alternative Estimators and Estimands in Volatility Modeling

- Factors in volatility profile
- Overnight returns instead of open-to-close
- Signal Recovery Perspective (Ferwana and Varshney [2022](#))
- Stochastic Volatility: Correlation between errors
- Multivariate GARCH

# What can you do with a volatility forecast?

- Value-at-Risk using SVF-based  $\hat{\sigma}_t^2$

# New Frontiers in Distance-based Weighting

- Integrate lessons from literature on under/over reactions to information shocks (Jiang and Zhu [2017](#))
- Distance-based Weighting of Impulse Response Functions

## Distance-based Weighting of Impulse Response Functions

Suppose

- We have a collection of  $p$ -variate time series of lengths  $T_i, i = 1, 2, \dots, n + 1$ .
- We are interested in the response of variable  $r$  to shocks in variable  $j, 1 \leq r \leq j \leq p$ .

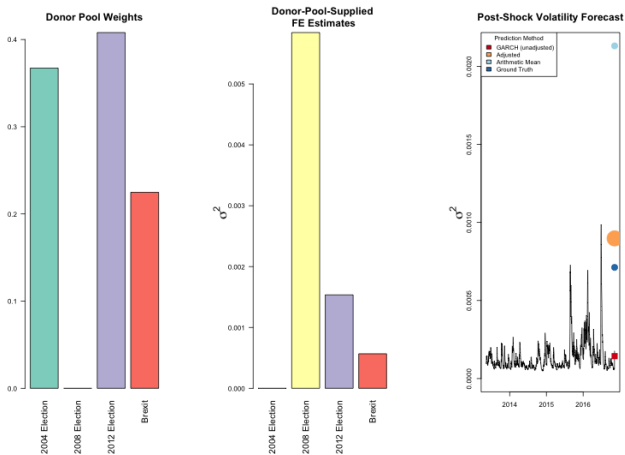

There many ways to estimate  $IRF_1(r, j)$ .

Can we somehow aggregate the estimates  $\widehat{IRF}_i(r, j), i = 2, 3, \dots, n + 1$ ?

Additional research questions:

- What DGP would best motivate/justify such a method?
- Which method of IRF estimation would perform best?

We analyze the real data example with Brexit included.
